

STIRRINGS IN THE POND by Dave and Gill Shearing

For those of us lucky enough to have a garden pond, March is the month when we see it starting to come to life after a dormant period over the Winter.

Although important, temperature is not the only factor that causes this awakening. Just as important is the day length, especially for the pond plants. Any pruning and tidying of marginal plants and deeper water plants such as water lilies should have been done during the Winter to minimize disturbance to Amphibians, Fish and invertebrates. Even if the plants were cut back severely in the Winter they will grow prolifically during the Spring.

Frogs mostly hibernate in the mud at the bottom of the pond and from about February onwards they can be seen in pairs on the surface spawning. Toads and Newts on the other hand will have spent the Winter in a shed, hole in a wall, mouse burrow or under piles of logs up to a mile from the pond and will have to travel overland back to the pond for spawning crossing busy roads in the process.

This happens mainly during the night and some village communities operate rescue schemes at this time of the year to assist them by carrying them across the dangerous roads. Toads will always return to the pond where they were born to spawn. Newts and Frogs are not so particular as long as the pond is suitable.

Great Silver Water Beetle

Many invertebrate species colonize a pond by flying in. These include many species of Beetle.

The largest is the scarce Great Silver Water Beetle, which can be up to two inches long. Unusual for a water Beetle, this one is a vegetarian.
